

# Recursion as a Problem-Solving Technique

## Chapter 5

# Contents

- Defining Languages
- Algebraic Expressions
- Backtracking
- The Relationship Between Recursion and Mathematical Induction

# Defining Languages

- A language is
  - A set of strings of symbols
  - From a finite alphabet.
- $\text{C++Programs} = \{\text{string } s : s \text{ is a syntactically correct C++ program}\}$
- $\text{AlgebraicExpressions} = \{\text{string } s : s \text{ is an algebraic expression}\}$

# The Basics of Grammars

- Special symbols
  - $x \mid y$  means  $x$  or  $y$
  - $xy$  (and sometimes  $x \cdot y$ ) means  $x$  followed by  $y$
  - $\langle \text{word} \rangle$  means any instance of  $\text{word}$ , where  $\text{word}$  is a symbol that must be defined elsewhere in the grammar.
- $\text{C++Identifiers} = \{\text{string } s : s \text{ is a legal C++ identifier}\}$

# The Basics of Grammars

# Recognition Algorithm for Identifiers

The initial call is made and the function begins execution.

`s = "A2B"`

At point X, a recursive call is made and the new invocation of `isId` begins execution.

`s = "A2B"`

X

`s = "A2"`

At point X, a recursive call is made and the new invocation of `isId` begins execution.

`s = "A2B"`

X

`s = "A2"`

X

`s = "A"`

...

FIGURE 5-2 Trace of `isId("A2B")`

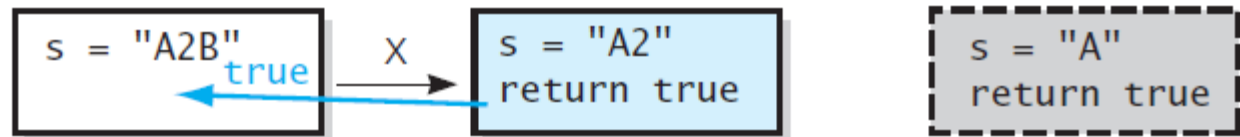

# Recognition Algorithm for Identifiers

...

This is the base case, so this invocation of `isId` completes:

The value is returned to the calling function, which completes execution:

The value is returned to the calling function, which completes execution:

FIGURE 5-2 Trace of `isId("A2B")`

# Two Simple Languages

- Palindromes = {string  $s$  :  $s$  reads the same left to right as right to left}
- Grammar for the language of palindromes:

$$\begin{aligned}\langle pal \rangle &= \text{empty string} \mid \langle ch \rangle \mid a \langle pal \rangle a \mid b \langle pal \rangle b \mid \dots \mid Z \langle pal \rangle Z \\ \langle ch \rangle &= a \mid b \mid \dots \mid z \mid A \mid B \mid \dots \mid Z\end{aligned}$$

# Two Simple Languages

- A recognition algorithm for palindromes

```
// Returns true if the string s of letters is a palindrome; otherwise returns false.  
isPalindrome(s: string): boolean  
  
    if (s is the empty string or s is of length 1)  
        return true  
    else if (s's first and last characters are the same letter)  
        return isPalindrome(s minus its first and last characters)  
    else  
        return false
```

# Algebraic Expressions

- Compiler must recognize and evaluate algebraic expressions

- Example

`y = x + z * (w / k + z * (7 * 6)) ;`

- Kinds of algebraic expressions
  - infix
  - prefix
  - postfix

# Algebraic Expressions

- infix
  - Binary operator appears between its operands
- prefix
  - Operator appears before its operands
- postfix
  - Operator appears after its operands

# Prefix Expressions

- Grammar that defines language of all prefix expressions

$$\langle \text{prefix} \rangle = \langle \text{identifier} \rangle \mid \langle \text{operator} \rangle \langle \text{prefix} \rangle \langle \text{prefix} \rangle$$
$$\langle \text{operator} \rangle = + \mid - \mid * \mid /$$
$$\langle \text{identifier} \rangle = a \mid b \mid \dots \mid z$$

# Prefix Expressions

The initial call `endPre("+*ab-cd", 0)` is made, and `endPre` begins execution:

first	= 0
last	= 6

First character of `strExp` is `+`, so at point `X`, a recursive call is made and the new invocation of `endPre` begins execution:

Next character of `strExp` is `*`, so at point `X`, a recursive call is made and the new invocation of `endPre` begins execution:

...

FIGURE 5-3 Trace of `endPre ( "+/ab-cd", 0)`

# Prefix Expressions

...

Next character of `strExp` is `a`, which is a base case. The current invocation of `endPre` completes execution and returns its value:

Because `firstEnd > -1`, a recursive call is made from point `Y` and the new invocation of `endPre` begins execution:

Next character of `strExp` is `b`, which is a base case. The current invocation of `endPre` completes execution and returns its value:

...

FIGURE 5-3 Trace of `endPre ( "+/ab-cd" , 0)`

# Prefix Expressions

...

The current invocation of `endPre` completes execution and returns its value:

Because `firstEnd > -1`, a recursive call is made from point Y and the new invocation of `endPre` begins execution:

Next character of `strExp` is `-`, so at point X, a recursive call is made and the new invocation of `endPre` begins execution:

...

FIGURE 5-3 Trace of `endPre ( "+/ab-cd" , 0)`

# Prefix Expressions

...

Next character of `strExp` is `c`, which is a base case. The current invocation of `endPre` completes execution and returns its value:

Because `firstEnd > -1`, a recursive call is made from point `Y` and the new invocation of `endPre` begins execution:

Next character of `strExp` is `d`, which is a base case. The current invocation of `endPre` completes execution and returns its value:

...

FIGURE 5-3 Trace of `endPre ( "+/ab-cd" , 0)`

# Prefix Expressions

...

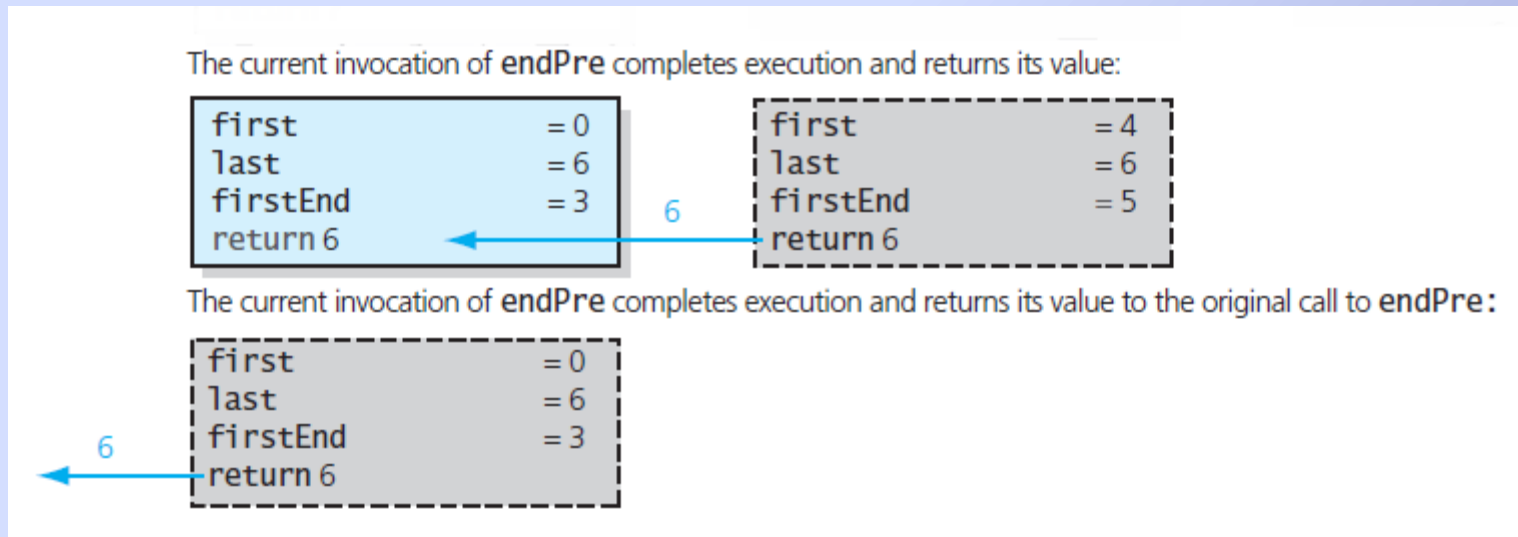

FIGURE 5-3 Trace of `endPre ( "+/ab-cd" , 0)`

# Postfix Expressions

- Grammar that defines language of postfix expressions

$$\begin{aligned}\langle postfix \rangle &= \langle identifier \rangle | \langle postfix \rangle \langle postfix \rangle \langle operator \rangle \\ \langle operator \rangle &= + | - | * | / \\ \langle identifier \rangle &= a | b | \dots | z\end{aligned}$$

# Fully Parenthesized Expressions

- Grammar that defines language of fully parenthesized infix expression

$$\begin{aligned}\langle infix \rangle &= \langle identifier \rangle \mid (\langle infix \rangle \langle operator \rangle \langle infix \rangle) \\ \langle operator \rangle &= + \mid - \mid * \mid / \\ \langle identifier \rangle &= a \mid b \mid . \mid \dots \mid z\end{aligned}$$

# Backtracking

- Consider searching for an airline route
- Input text files that specify all of the flight information for HPAir Company
  - Names of cities HPAir serves
  - Pairs of city names, each pair representing origin and destination of one of HPAir's flights
  - Pairs of city names, each pair representing a request to fly from some origin to some destination

# Backtracking

FIGURE 5-4 Flight map for HPAir

# Backtracking

- A recursive strategy

*To fly from the origin to the destination:*

*Select a city C adjacent to the origin*

*Fly from the origin to city C*

**if** (C is the destination city)

*Terminate—the destination is reached*

**else**

*Fly from city C to the destination*

# Backtracking

- Possible outcomes of applying the previous strategy
  1. Eventually reach destination city and can conclude that it is possible to fly from origin to destination.
  2. Reach a city C from which there are no departing flights.
  3. Go around in circles.

# Backtracking

- And inspect an implementation of **placeQueen**, [Listing 5-D](#)

# Correctness of the Recursive Factorial Function

- A recursive function that computes the factorial of a nonnegative integer  $n$

```
fact(n: integer): integer
    if (n is 0)
        return 1
    else
        return n * fact(n - 1)
```

# Correctness of the Recursive Factorial Function

- Assume property true for  $k = n$

$$\text{factorial}(k) = k! = k \cdot (k-1) \cdot (k-2) \cdot \dots \cdot 1$$

- Now show

$$\text{factorial}(k+1) = (k+1) \cdot k \cdot (k-1) \cdot (k-2) \cdot \dots \cdot 2 \cdot 1$$

# The Cost of Towers of Hanoi

- Recall solution to the Towers of Hanoi problem

```
solveTowers(count, source, destination, spare)
    if (count is 1)
        Move a disk directly from source to destination
    else
    {
        solveTowers(count - 1, source, spare, destination)
        solveTowers(1, source, destination, spare)
        solveTowers(count - 1, spare, destination, source)
    }
```

# The Cost of Towers of Hanoi

- Consider ... begin with  $N$  disks, how many moves does **solveTowers** make to solve problem?

- We conjecture 
$$\text{moves}(N) = 2^N - 1 \quad \text{for all } N \geq 1$$

- Make assumption for  $N = k$

- Must show

$$\text{moves}(k + 1) = 2^{k+1} - 1$$

# End

## Chapter 5
